

BPSFI - Object Search First in Buffer Pool

This Natural profile parameter is for:

- mainframes
- UNIX/OpenVMS and Windows

With this parameter, you determine the sequence in which a requested object that is to be executed is searched for in the buffer pool and in the system file(s). You can choose between two search sequences:

Possible settings	ON	Search Sequence 1 is used (search buffer pool first for all libraries, then the system file(s)). Natural looks for the object in the following sequence until it is found: 1. in the buffer pool, first in the current library, then in one steplib after another, then in the two SYSTEM libraries; 2. in the system file(s), first in the current library, then in one steplib after another, then in the two SYSTEM libraries.
	OFF	Search Sequence 2 is used (alternating search in buffer pool and system file(s) for each library). Natural looks for the object in the following sequence until it is found: 1. in the current library, first in the buffer pool, then in the system file(s); 2. in one steplib after another, first in the buffer pool, then in the system file(s) for each steplib; 3. in the two SYSTEM libraries, first in the buffer pool, then in the system file(s) for each library.
